COMPARATIVE CHARACTERISTICS OF THE PHYSICAL TRAINING OF WOMEN BETWEEN 30 AND 49 YEARS OF AGE BASED ON INDICATORS OF PHYSICAL TRAINING DEPENDING ON THE BODY WEIGHT FAT COMPONENT CONTENT

Svitlana Salnikova ¹

¹ Assistant Lecture in Law Chair of Vinnytsia Trade and Economy Institute, Vinnytsia, Ukraine, Ukraine, aqvaveta@ukr.net

The current relevance of the research. The paper is devoted to the research of fat body content influence on the parameters of physical state at 30-years women. It was determined that increasing of fat body content at 30–49 years women negatively affects speed, active spine flexibility, explosive strength, agility, power dynamic endurance of muscles of upper limb girdle and lower extremities, speed-power endurance of abdominal muscles, static fatigue of gluteal muscles and total endurance. Goal of research is to investigate the parameters of physical preparation of 30–49 years women depending on fat body content. Results of research: It is established the dependence between speed, active spine flexibility, explosive strength, agility, power dynamic endurance of muscles of upper limb girdle and lower extremities, speed-power endurance of abdominal muscles, static fatigue of gluteal muscles, total endurance and fat body content. The increasing fat body content at 30–36 years women leads to more negative effects compare to 37–49 years women. Conclusions. It is proved the reasonability of creation of special water fitness program for 30–49 years women. The purpose of such program is improving of physical qualities.

Key words: physical preparation, physical qualities, makeup of body mass fat content.

Світлана Сальникова. Порівняльна характеристика фізичного стану жінок 30–49 років за показниками фізичної підготовленості залежно від умісту жирового компонента маси тіла. Актуальність. У статті досліджено вплив умісту жирового компонента маси тіла на показники фізичної підготовленості в жінок 30–49 років. Установлено, що перевищення жирового компонента в жінок 30–49 років негативно вплинуло на прояв швидкості, активної гнучкості хребта, вибухової сили, спритності, силової динамічної витривалості м’язів плечового пояса й нижніх кінцівок, швидкісно-силової витривалості м’язів черевного преса, силової статичної витривалості сідничних м’язів та загальної витривалості. Завдання роботи – дослідити показники фізичної підготовленості жінок 30–49 років залежно від умісту жирового компонента маси тіла. Результати роботи. Установлено залежність прояву швидкості, активної гнучкості хребта, вибухової сили, спритності, силової динамічної витривалості м’язів плечового пояса й нижніх кінцівок, швидкісно-силової витривалості м’язів черевного преса, силової статичної витривалості сідничних м’язів і загальної витривалості від умісту жирового компонента. Перевищення вмісту жирового компонента в жінок 30–36 років призводить до більш негативних наслідків, ніж у 37–49-річних. Висновки. Доведена доцільність розробки програми заняттів аквафітнесом для жінок 30–49 років, спрямованих на покращення фізичних якостей, які зазнають найбільших інволюційних змін.

Ключові слова: фізична підготовленість, фізичні якості, компонентний склад маси тіла, жировий компонент.

Сальникова Світлана. Співвідношена характеристика фізичного стану жінок 30–49 років за показниками фізичної підготовленості в залежності від вмісту жирових компонентів маси тіла. Актуальність. В статті через розглянуто вплив жирового компонента маси тіла на показники фізичної ладності у жінок 30–49 років. Установлено, що превищення жирового компонента у жінок 30–49 років негативно повлинуло на прояв швидкості, активної гнучкості позвоночника, взрывої сили, локвостності, силової динамічної висноюлості м’язів плечового пояса і нижніх конечностей, скоростно-силової висноюлості м’язів брюшного преса, силової статичної висноюлості ягоди м’язи і загальної висноюлості від умісту жирового компонента. Завдання роботи – дослідити показники фізичної підготовленості жінок 30–49 років в залежності від вмісту жирових компонентів маси тіла. Результати роботи. Установлено залежність прояву швидкості, активної гнучкості позвоночника, взрывої сили, локвостності, силової динамічної висноюлості м’язів плечового пояса і нижніх конечностей, скоростно-силової висноюлості м’язів брюшного преса, силової статичної висноюлості ягоди и загальної висноюлості від умісту жирового компонента. Превищення вмісту жирового компонента в жінок 30–36 років призводить до більш негативних наслідків, ніж у 37–49-річних. Висновки. Доведена доцільність розробки програми заняттів аквафітнесом для жінок 30–49 років, спрямованих на покращення фізичних якостей, які зазнають найбільших інволюційних змін.

**Introduction.** The problem of preserving and improving the physical health of women after 30 years is due to the subsequent activation of professional, creative and social activities, and the necessity to increase their longevity and preservation prior to menopause full reproductive function [16]. According to leading experts, since 30 years, women advisable to use such means of physical training, which would improve the physical state by stimulating aerobic processes of energy, increasing energy of physical work [7; 8; 16], reducing gravitational effects on cartilage formation joints and hardening of the body [9; 10; 12].

According to the Committee of international standardization of tests, physical state characterized by a state of health, physique, constitution functional possibilities of the body, physical work and physical training [5].

However, O. Pirogov, L. Ivashchenko, N. Strapko consider the physical state, as a human willingness to do physical work at home, at work, in physical training or sport. This approach to the definition of «physical state» reveals the following factors that influence on its level: physical capacity, physical development, functional and physical training, and for its assessment should take into account age and gender [1; 5; 14; 16].

To determine the major factors that characterize the physical state, informative selection criteria, developing shades, effective training programs aimed at improving it, O. Pirogov, L. Ivashchenko, N. Strapko had done multifactorial, numerous correlation and regression analysis of the indicators that reflect the physical development, physical training and morphofunctional state of the body [9].

S. Vasilenko stresses that the most simple, affordable and informative indicators characterizing the status of nutrition and health, is a mass index of the body (BMI) and percentage fat component in the body. With increasing, mass index and amount of fat in the body worse the physical capacity and adaptive potential of the circulatory system. E. Martyrosov and colleagues noted that a body has a significant correlation with indicators of physical capacity and the ability to adapt to environmental conditions, professional and sport activities.

Some scientists believe that it is advisable to assess the physical state of qualitative parameters of motor activity, namely for endurance, strength, speed, agility, flexibility, that is, the level of physical training [15].

According to the Concept of the National Program «Health 2020: Ukrainian dimension» about 60 % of the adult population of Ukraine has poor health. According to scientific research, the level of physical health of men in terms of maximum oxygen consumption (VO2max) and life expectancy is lower than of women [14].

On the other hand, according to M. Bulatov [5], the incidence rate of Ukrainian women on 12 % higher than in men it is reflected on quality of life, particularly in reducing the physical and mental capacity, reproductive function, psychological problems [2; 10; 12].

In addition, the average life expectancy of Ukrainian woman is much lower than for women in developing countries. Most scientists believe that the main reason for this phenomenon is the limited physical activity of women.

However, scientifically it had been proven that under the influence of physical training may resume physical capacity and physical training for people from 30 to 50 [9].

**The goals** of our scientific research is to develop the programs of aqua fitness to improve the physical properties that undergo major changes of aging because of the results of comparing the level of physical training of women 30–49 years depending on the component composition of body weight.

To achieve this goal settled the following tasks:

- to explore the indicators of physical training of women 30–36 and 37–49 years depending on the content of fat component weight.

**Methods and organization of our research:**

- the method of bioimpedansometry;
- pedagogical testing of physical training;
- methods of mathematical statistics.

The investigation of physical training was conducted considering the phase of the menstrual cycle. All researches studies were conducted after the menstrual phase (6-12 days after completion of menstruation) and after ovulation phase (days 16-24 at the end of menstruation). The investigations of women are carried out in phase’s ovulation and menstruation (12–13 days after cessation of menstrual phase) due to deterioration of efficiency and coordination [1].

This researches clasp 107 women aged 30–49, previously not involved of aqua fitness. 58 people are from 30 to 36 years and 49 people are from 37 to 49 year old.

For the purpose of research, we formed two age groups of women: younger (30–36 years) and older (37–49 years).
From among women 30–36 years, 19 people have «normal» content of fat component, 31 – «high» 8 – «very high». In the older age group «normal» fat component has been recorded for 11 women and «high» and «very high» have 17 and 21 respectively.

The physical capacity of studying women was evaluated by the following indicators of physical training as: speed (running at 30 meters from the high start); explosive power (long jump from their seats); agility (shuttle run 4×9 m); dynamic power endurance of muscles of the shoulder girdle (flexion-extension arms in emphasis lying on gymnastic bench) and lower limb (flexion-extension legs to a standing position, holding the chair); speed-strength endurance abdominal muscles (flexion-extension of the legs as fast as possible, lying on the gym bench times for 15 s); static strength endurance of back muscles and neck (hold «to failure» posture «lying on his stomach with raised up and slightly dilute straight legs and hands») and gluteal muscles (hold «to failure» posture «lying on his stomach with a maximum raised above the couch, at 10º parted and knees bent at an angle of 45º feet, holding hands on the couch»); active flexibility of the spine (torso forward from a standing position, fingers touching the mark of measuring instrument) and overall endurance.

According to the opinion of scientists about inappropriate of using the tests, using of which makes it possible to determine the overall endurance in untrained individuals [1;15], for the prevention of acute pathological states including complications of function of the cardiovascular system, and despite the fact that aqua fitness held in aqueous medium, we are not used running tests, replacing them the test of 12-minute swimming [8].

For evaluation and analysis of the results we compared tied sampling, where the series reflect the difference characteristics depending on age. The difference of average values of physical training was performed by the t-test of Student [6]. The difference was considered at the level of significance of p <0,05.

Discussion and the results of the study. The results of physical training of women 30-36 years and 37–49 led to the conclusion about the absence of age’s differences for representatives of both group in such physical qualities as strength of muscle flexor fingers and overall endurance.

The results of our research of physical training of women in both age groups depending on the component composition of body weight show some differences manifestation of motor characteristics in women 30-36 years compared with 37–49-year-old.

Women of younger age group the exceeding of fat component had affected on the active flexibility of spine, explosive strength, agility, dynamic power endurance of muscles of the shoulder girdle and legs, speed-strength endurance abdominal muscles, the static power endurance and gluteus muscles general endurance (table 1).

For the representatives of older age group on the content of fat component such physical quality as speed was depend. However, the level of fat component for women 37–49 did not effect on the expression of other indicators of physical training.

As we can see from Table 1, studying women of 37–49 years old, who had a «high» content of fat component, the result of running on 30 m from high start was at 4,45 % significantly lower than of women with «normal» content of this component.

The research of the ability to show of explosive force in women with different content of fat component had shown that exceeding of standards of this component of body weight of women 30–36 noticeably effect on the results of the test «long jump from place» than for women of 37–49 years old.

The result of the test «flexion-extension legs, lying on the gym bench for 15s.» for women of 37–49 with «very high» content of fat component is to 24,37 % significantly lower than those who had «normal» content.

The result of the test «flexion-extension legs to a standing position, holding the chair» was also significantly lower (by 24,97 %) compared with representatives of the «high» level of fat component (see. table 1).

Women 30–36 years with «normal» content of fat component have the test’s result «long jump from their seats» at 8,57 % (p <0,05) better than who has the «high» content of this component, and more those who have «very high» content – by 21,18 % (p <0,05). And the difference between this indicator also are registered in women with a «very high» and «high» content of fat component (by 11,61 %).

On the negative impact of fat component on the manifestation of women of 30–36 years indicates the presence of probable outcome differences shuttle race 4×9 m for women with «normal» content of fat component than those whose component is much higher than normal (2,99 %) (see. table 1).

A comparative analysis of the dynamic manifestation of power endurance of muscles of the shoulder girdle by the test «flexion-extension arms in emphasis lying on gymnastic bench» also showed that
exceeding the standards of fat component increasingly has the negative influence on the results of women of 30–36 than for women 37–49 year.

</table>

The result of this test was worse for individuals of 30–36 years with «high» and «very high» content of fat component compared with those who had «normal» content of fat component, respectively 33.48 and 85.24 % (p < 0.05).

Unlike the women of 30–36, for women of 37–49 years the content of fatty component has no significantly influence on the result of the test.

The result of the power dynamic endurance of the muscles of the lower extremities for women 30–36 years with «normal» content of fat component significantly exceeded average values of those whose content was «very high» (at 44.32 %) and «high» (43.29 %).

The index of speed-strength endurance abdominals by the test «flexion-extension of the legs as fast as possible, lying on the gym bench for 15 seconds» among the women 30–36 was to 22.80 % significantly lower in those who had a «very high» content of fat component, compared with those whose content was defined as «normal».

We found the dependence of static power endurance gluteus muscles on the content of fat component for women 30–36 years. Thus, for women in this age group who had «very high» content of these components, the duration of the maintenance posture «lying on his stomach with the highest elevated above a couch, diluted to 10º and bent at the knees at an angle of 45º feet, holding hands on the couch» was lower at 37.88 % if to compare with women whose component did not exceed the rate (p <0,05).

Studying the flexibility of women 30–36 years with different content of fat component also revealed the dependence of the test’s result «torso forward from a standing position, fingers touching the mark of measuring device» on the content of the component.

Thus, for the representatives of the youngest age group the «very high» content of fat component, comparing with those who had «normal» and «high» the active flexibility of the spine was worse respectively 2,31 and 1.86 times (p <0 , 05). It should be noted that for women 30-36 exceeding of the specified component influence to the reducing of such qualities as flexibility, more than for women of 37–49 years.

Unlike for women of 37–49 years, in which the content of fat component does not affect on the result of the test of 12-minute swimming by K.Cooper, for the women of 30–36 increasing of this component to ‘very
high' has negative impact on the manifestation of endurance. Thus, the result of this test was worse to 37.88 % (p<0.05) in participants with «very high» content of fat component, comparing with «normal».

Conclusions. The analysis of the results of our research shows that women of 30–49 have the manifestation of physical properties from content of fat component. The exceeding of fat component in younger women leads to more negative outcomes than older women. Thus, the exceeding of fat component for women 30–36 years has negatively effect on the expression of speed, active flexibility of the spine, explosive strength, agility, dynamic power endurance of muscles of the shoulder girdle and legs, speed-strength endurance abdominal muscles, the static power endurance glutei muscles and overall endurance. For women of 37–49 with exceeding of fat component deteriorated only dynamic power endurance of muscles of the lower extremities and speed-strength endurance abdominal muscles. For women of 37–49, opposite to 30–36, the exceeding of fat component had not affect to the display of dexterity.

So, in order to improve the physical capacity of women 30–49 years old, appropriate to develop the programs of aqua fitness training that would help to improve the physical qualities.

Prospects for further research. Further studies will be used to study the dependence of physical training from the content of muscle component of body weight for women of 30–49 years old.
